

Although most reported cases showed the fistula arising from the right side of the tracheobronchial tree, in the present case it arose from the left side. All cases reported in the literature terminated in the left lobe of the liver.

Investigation of a child with a suspected bronchobiliary fistula should include bronchoscopy, bronchography and HIDA scanning. It is important to ascertain whether the affected lobe of the liver drains normally, as hepatic resection of the involved lobe may be necessary in addition to resection of the fistula.<sup>6</sup> A right thoracotomy can be used in every case, and in the present case a Fogarty catheter placed via bronchoscopy was helpful in identifying the fistula. Bronchobiliary fistula should be suspected in the

child with bilious reflux without evidence of obstruction.
