Tubular duplication of the esophagus

A 6-year-old boy presented to the emergency department with an impacted foreign body in the esophagus. His medical history was marked by a mild dysphagia for solid food, present since the age of 2 years. His physical examination was unremarkable.

An upper endoscopy was performed. After a coin in the esophagus was removed, an esophageal stenosis and an orifice in the esophageal wall were noticed (Fig. 1). Biopsy of the double lumen showed chronic esophagitis. A barium esophagram (Fig. 2) was also carried out and contributed to a diagnosis of tubular duplication of the esophagus.

Esophageal duplication is a rare congenital anomaly with an estimated incidence of 1 in 8200, representing about 10% of all foregut duplications.¹⁻³ The cystic form is the most usual presentation of the duplication, whereas the tubular type accounts for only 5%–10% of cases.⁴ Esophageal duplication cysts are commonly found in the lower third (60%–95%) and on the right side,^{1,5} whereas the tubular form is frequently reported in the middle and lower esophagus.^{1,4,6,7}

The duplication may be discovered incidentally in adulthood^{1,3,4,6,8}; however, from 70%–90% of the cases present before 2 years of age.^{7,8}

The most frequent symptoms are dysphagia, digestive hemorrhage, retrosternal pain and, especially, respiratory symptoms (recurrent pneumonia, stridor, respiratory distress) that may be present in more than 80% of the cases.⁷ Vertebral anomaly may be associated with the disease.^{4,7,9} This type of association may be explained in terms of notochordodysraphy (split notochord syndrome), the result of an abnormal

division of the notochord in the third week of embryogenesis.¹⁰ However, Bremer¹¹ suggests an error associated with

the vacuolization of the esophagus in the fifth and seventh weeks of embryogenesis.

The diagnosis may be carried out by

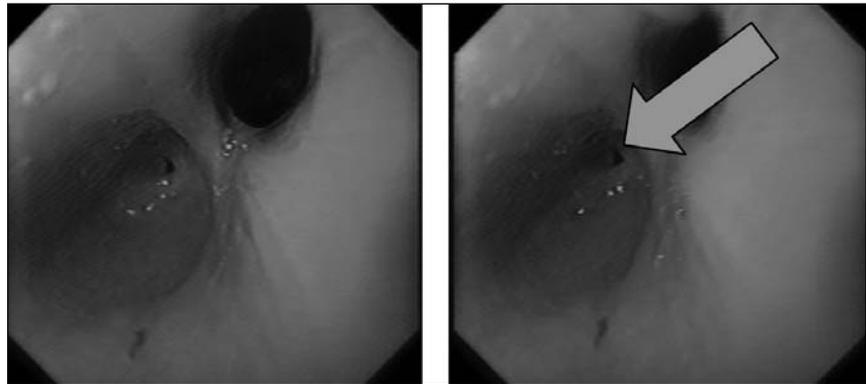

FIG. 1. Upper endoscopy of the esophagus reveals an esophageal stenosis and an orifice in the esophageal wall (arrow).

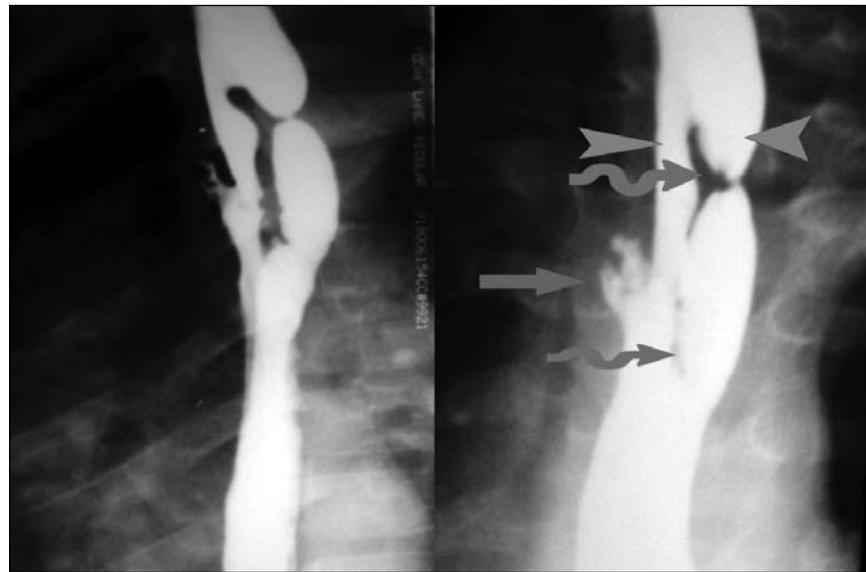

FIG. 2. Barium esophagram contributed to a diagnosis of tubular duplication of the esophagus: diverticulum (arrow), double lumen (arrowheads), septum (curved arrows).

means of an esophagram,^{4-7,9} upper endoscopy and computed tomography scan.^{1-3,8} An endoscopy is used to perform a biopsy in the double lumen of the esophagus and may reveal an ectopic mucosa.⁶ In our case, the esophageal duplication was diagnosed by endoscopy and esophagram, which are the most commonly performed examinations in the diagnosis of the tubular form of the duplication. Magnetic resonance imaging contributes by following the double lumen throughout its length and by revealing the communication with the esophageal lumen, clarifying the anomalous anatomy.^{2,4}

Surgical treatment has been recommended by some authors because of the risk of malignization.^{3,7,12,13} Other authors suggest surgical treatment only in the presence of symptoms.^{1,2,7} Extensive surgery such as esophagectomy is usually required for the tubular forms. Recently, a laparoscopic approach for resection of cystic forms has been reported.¹⁴

THE MACLEAN-MUELLER PRIZE

Attention: Residents and surgical department chairs

Each year the *Canadian Journal of Surgery* offers a prize of \$1000 for the best manuscript written by a Canadian resident or fellow from a specialty program who has not completed training or assumed a faculty position. The prize-winning manuscript for the calendar year will be published in an early issue the following year, and other submissions deemed suitable for publication may appear in a subsequent issue of the Journal.

The resident should be the principal author of the manuscript, which should not have been submitted or published elsewhere. It should be submitted to the *Canadian Journal of Surgery* not later than Oct. 1.

Send submissions to: Dr. J.P. Waddell, Coeditor, *Canadian Journal of Surgery*, Division of Orthopædic Surgery, St. Michael's Hospital, 30 Bond St., Toronto ON M5B 1W8.
